25 **Abstract:** Mutualisms between plants and ants are common features of tropical ecosystems  
26 around the globe and can have cascading effects on interactions with the ecological communities  
27 in which they occur. In an African savanna, we assessed whether acacia ants influence nest site  
28 selection by tree-nesting birds. Birds selected nest sites in trees inhabited by ant species that  
29 vigorously defend against browsing mammals. Future research could address the extent to which  
30 hatching and fledging rates depend on the species of ant symbiont, and why ants tolerate nesting  
31 birds but not other tree associates (especially insects).

32

33 **Key words:** *Crematogaster* spp., gray-capped social weaver (*Pseudonigrita arnaudi*), gray-  
34 headed sparrow (*Passer griseus*), Kenya, plant-ant mutualisms, superb starling (*Lamprotornis*  
35 *superbus*), symbioses, *Tetraoponera penzigi*

36

LUJAN, NIELSEN, et al.

37 Mutualisms structure biodiversity and ecosystem function (Stachowicz 2001). Mutualisms  
38 between plants and ants are particularly widespread across the tropics (Christian 2001,  
39 Frederickson *et al.* 2005, Palmer & Brody 2013, Prior *et al.* 2015), including the savannas of  
40 East Africa (Young *et al.* 1996, Stanton & Palmer 2011, Palmer & Brody 2013, Hays *et al.*  
41 2022). In such ecosystems, whistling thorn trees (*Acacia [Vachellia] drepanolobium*) form a  
42 near-monoculture, comprising 95-99% of the canopy layer (Young *et al.* 1996). Four ant species  
43 (*Crematogaster mimosae*, *C. nigriceps*, *C. sjostedti*, and *Tetraponera penzigi*) are symbionts of  
44 whistling thorn trees, which produce extrafloral nectar and swollen-thorn domatia to recruit and  
45 maintain colonies (Palmer *et al.* 2008).

46 Ant species exclusively occupy host trees, with a single species typically controlling the  
47 canopies of individual trees at any given time. Further, the four ant species vary in the benefits  
48 they provide and costs they impose to host trees. *Crematogaster mimosae* and *C. nigriceps*  
49 aggressively defend trees against mammalian and insect herbivores, and they are particularly  
50 effective at deterring catastrophic (lethal) herbivory by elephants (*Loxodonta africana*; Goheen  
51 & Palmer 2010, Palmer & Brody 2013). By sterilizing its host trees, *C. nigriceps* additionally  
52 functions as a short-term (one to several years) parasite, but it enhances lifetime fitness by  
53 offering protection to otherwise vulnerable, pre-reproductive trees (Stanton *et al.* 1999, Palmer *et*  
54 *al.* 2010). In contrast, *T. penzigi* and *C. sjostedti* provide only moderate to minimal protection,  
55 respectively, against herbivory (Palmer & Brody 2007, Palmer *et al.* 2010).

56 Despite the ants' presence, several bird species—such as gray-capped social weavers  
57 (*Pseudonigrita arnaudi*), gray-headed sparrows (*Passer griseus*), and superb starlings  
58 (*Lamprotornis superbus*)—often nest in whistling thorn trees. Although birds nest in ant-  
59 defended acacias in Central America (Janzen 1969, Young *et al.* 1990, Flaspohler & Laska 1994,

LUJAN, NIELSEN, et al.

LUJAN, NIELSEN, et al.

60 Oliveras de Ita & Rojas-Soto 2006), ants are nest predators (Smith *et al.* 2007, Menezes &  
61 Marini 2017) and can deter birds from feeding in ant-defended trees (Haemig 1994, Aho *et al.*  
62 1997, Philpott *et al.* 2005). These contrasting observations from the Neotropics generate distinct  
63 predictions regarding whether and how birds distinguish among host trees occupied by different  
64 ant symbionts. If acacia ants defend against all disturbances to host trees, then birds should select  
65 trees occupied by less aggressive symbionts (i.e., *C. sjostedti* and *T. penzigi*, to a lesser extent)  
66 for nesting. However, it also is possible that acacia ants confer protection to bird nests, in which  
67 case birds should select for trees with aggressive symbionts (i.e., *C. mimosae* and *C. nigriceps*).

68 To uncover associations between birds and acacia ants, we systematically searched for  
69 bird nests in whistling thorn savannas at Mpala Research Centre and Conservancy (0°17' N,  
70 36°53' E), Laikipia, Kenya in June 2022. We identified species by nest architecture: gray-capped  
71 social weavers build spherical nests with bottom-facing entrances (usually with multiple nests in  
72 the same tree), while superb starlings and gray-headed sparrows build gourd-shaped nests with  
73 side-facing entrances (usually with one nest per tree). Nests of superb starlings and gray-headed  
74 sparrows can be distinguished by the size of the entrance (starling nests have entrances large  
75 enough to fit a hand into, while entrances of sparrow nests are smaller). For each “used” tree in  
76 which we found bird nests, we identified the four nearest neighbors above 0.5 m tall, classifying  
77 these as “available”. For both used and available trees, we measured tree height, diameter at 30  
78 cm from the base, whether the tree was alive or dead, canopy area (calculated by measuring the  
79 width and length of the canopy and estimating its area, where  $\text{area} = \pi * \text{width} * \text{length}$ ), and the  
80 species of ant symbiont occupying the tree. We performed logistic regression to quantify the  
81 influence of these predictors on nest tree selection and calculated variance inflation factors to  
82 check for multicollinearity among predictors.

83           Some of these ant species (particularly *C. sjostedti* and *C. mimosae*) are spatially  
84 clustered on the landscape and inordinately likely to inhabit neighboring trees. To ensure that  
85 such spatial autocorrelation did not bias our results, we also conducted a second logistic  
86 regression in which we substituted the available trees we described above for a new set of  
87 available trees that were < 0.5 m tall and located within 10 m of glades (nutrient-rich, open  
88 grazing lawns that form after livestock graze the area for an extended period of time) or termite  
89 mounds. Nests were typically found within or near these landscape features. This second set of  
90 available trees was surveyed for previous research (Palmer *et al.* 2010), and data were only  
91 available for height and ant species occupant.

92           We used the ‘car’ package (v3.0.12; Fox & Weisberg 2019) to calculate variance  
93 inflation factors and the R statistical software environment (v4.2.1; R Core Team 2020) to  
94 perform all statistical analyses.

95           We located 60 nests in total (34 superb starling, 16 gray-headed sparrow, 8 gray-capped  
96 social weaver, and 2 cup nests created by unknown species). Of these nests, 45 were located in  
97 trees inhabited by *Crematogaster mimosae*, 14 in trees inhabited by *Crematogaster nigriceps*,  
98 and 1 in a tree inhabited by *Crematogaster sjostedti*. All nests were in live trees that were more  
99 than 1.5 m in height.

100           Our first logistic regression model identified height ( $\beta = 0.002$ ;  $p < 0.0001$ ) and  
101 occupancy by *C. nigriceps* ( $\beta = 0.17$ ;  $p < 0.01$ ) as the most important predictors of nest selection  
102 (Table 1; Fig. 1A). For each 1 m increase in height, the odds that birds nested in a tree increased  
103 by 20% (95% CI: 12 – 29%). The odds that birds nested in a tree inhabited by *C. nigriceps* were  
104 18% higher than for those inhabited by *C. mimosae* (the reference category; 95% CI: 5 – 34%).  
105 Other predictors were not significant.

106 Our second logistic regression model did not identify height as an important predictor of  
107 nest selection ( $\beta = 0.04$ ;  $p = 0.09$ ), but it did identify ant species as an important predictor.  
108 Compared to trees inhabited by *C. mimosae*, the odds that trees inhabited by *C. nigriceps*  
109 contained nests were roughly equal (95% CI: -3 – 34%), but the odds that trees inhabited by *C.*  
110 *sjostedti* contained nests were 27% lower (95% CI: 17 – 35%), and the odds that trees inhabited  
111 by *T. penzigi* contained nests were 26% lower (95% CI: 13 – 37%).

112 Birds almost always nested in trees inhabited by aggressive defenders of host trees (*C.*  
113 *nigriceps* and *C. mimosae*), particularly *C. nigriceps* (Table 1, Fig. 1). The selection of nesting  
114 sites inhabited by more aggressive ant species may reduce risk of nest predation (Young *et al.*  
115 1990), which can reduce lifetime fitness in birds (Freeman *et al.* 2020; Martin 1993). Future  
116 research with longitudinal data on nest survival may elucidate the fitness benefits of ant  
117 symbionts for birds.

118 Tree architecture likely plays an important role in nest site selection by birds. In addition  
119 to protecting whistling thorn trees from herbivory, some acacia ants change the architecture of *A.*  
120 *drepanolobium*. Because *Crematogaster nigriceps* is an inferior competitor to other  
121 *Crematogaster* spp., it prunes apical buds, which shortens shoots and reduces the likelihood of  
122 contact with host trees occupied by *C. nigriceps* and *C. sjostedti* (Stanton *et al.* 1999). As such,  
123 occupancy by *C. nigriceps* results in substantially denser canopies, which likely provide  
124 concealment and further protection from predators (see also Oliveras de Ita & Rojas-Soto 2006,  
125 Latif *et al.* 2012), which include snakes, mesocarnivores, and raptors (W. Watetu, pers. obs.).

126 Although *C. mimosae* and *C. nigriceps* vigorously defend their host trees from both  
127 vertebrate and invertebrate herbivores, and some ants are nest predators (e.g., Suarez *et al.* 2005,  
128 Smith *et al.* 2007, Menezes & Marini 2017), *C. mimosae* and *C. nigriceps* apparently attack

LUJAN, NIELSEN, et al.

LUJAN, NIELSEN, et al.

129 neither nestlings nor adult birds (W. Watetu, pers. obs.). Acacia ants can distinguish between  
130 wind-induced and herbivore-induced vibrations (Hager & Krausa 2019), but ants readily attack  
131 humans manipulating bird nests. The cues ants use to differentiate birds from herbivores against  
132 which they defend trees remain unclear, but our study suggests that either ants can distinguish  
133 between sources of vibrations even better than is currently appreciated, that other cues (e.g.,  
134 chemical or visual cues) may also trigger ant defense of trees, or that bird nests have chemical or  
135 structural characteristics that deter ants from entering them.

136         Birds are not the only occupants of *A. drepanolobium*, and acacia ants may influence the  
137 ecology of other *A. drepanolobium* inhabitants as well. Several arboreal reptiles inhabit *A.*  
138 *drepanolobium*, and the most common of these (*Lygodactylus keniensis*, a gecko) selects for  
139 trees inhabited by the least aggressive ant, *C. sjostedti* (Pringle *et al.* 2015), perhaps because the  
140 more aggressive ant species inhibit the elephant damage that creates the gecko's preferred  
141 microhabitats (Pringle 2008). It is possible that acacia ants similarly influence habitat selection  
142 by the other, less common arboreal reptiles in this system, by directly defending trees from  
143 animals moving in them, by influencing patterns of tree damage and herbivory by large  
144 herbivores, or by altering the architecture of tree canopies. Ants could likewise influence the use  
145 of *A. drepanolobium* by the other animals known to inhabit these trees, including other bird  
146 species, primates, and invertebrates.

147         In summary, birds in an East African whistling thorn savanna select nest sites in trees  
148 defended by the most aggressive acacia ants, particularly a species (*C. nigriceps*) that alters tree  
149 architecture such that the canopy is denser. This raises questions for future work: Are birds  
150 selecting nest trees based on the aggressiveness of ant symbionts *per se*, correlates of ant  
151 symbionts (like the denser architecture of trees inhabited by *C. nigriceps*), or both? Do ant

LUJAN, NIELSEN, et al.

LUJAN, NIELSEN, et al.

152 symbionts differentially affect hatching and fledging rates? How do ants distinguish between  
153 birds and other animals they defend trees against? Do the acacia ants benefit other animal species  
154 that also inhabit these trees? Further research to answer these questions may reveal much more  
155 about how mutualisms operate, and cascading effects for other species in interaction webs.

156

### 157 **Acknowledgments**

158 We thank Mpala Research Centre for hosting the field course during which we collected data and  
159 A. Klass for assisting with field data collection. Financial support was provided by the  
160 University of Wyoming's Center for Global Studies, the University of Wyoming's Biodiversity  
161 Institute and a National Science Foundation grant to TMP (DEB 1149980).
